Background

The set of k -dimensional subspaces of \mathbb{C}^n is called the Grassmannian. Modern Schubert calculus aims to study its geometry through its (connective) K -theory ring. The Schubert structure sheaf basis is represented by **symmetric Grothendieck polynomials** $\mathfrak{G}_\lambda(\mathbf{x}; \beta)$, which form a basis for the ring of symmetric functions. A. Buch has shown that $\mathfrak{G}_\lambda(\mathbf{x}; \beta)$ can be given as a sum over **set-valued tableaux** $\text{SV}^n(\lambda)$, fillings of λ with nonempty subsets of $\{1, \dots, n\}$ such that rows are weakly increasing and columns strictly increasing in the following sense:

$$\begin{array}{|c|c|} \hline X & Y \\ \hline Z & \\ \hline \end{array}, \quad \text{where } \max(X) \leq \min(Y) \text{ and } \max(X) < \min(Z).$$

Grothendieck polynomials at $\beta = 0$ are precisely the Schur polynomials since β counts the **excess**, how far a set-valued tableau is from being semistandard. Furthermore they are known to be Schur positive. Thus, a natural question is to determine a crystal structure, in the sense of Kashiwara, on set-valued tableaux. Since a product of Grothendieck polynomials is a finite positive sum of Grothendiecks, there should further be an extension of a crystal structure and the tensor product rule where $\text{SV}^n(\lambda)$ become the irreducible objects that realizes the representation of some quantum group. One application of our proposed K -crystal structure is to study the more mysterious so-called **Lascoux polynomials**

$$L_{w\lambda}(\mathbf{x}; \beta) := \varpi_{i_1} \cdots \varpi_{i_\ell} \mathbf{x}^\lambda, \quad \text{where } \varpi_i = \frac{x_i(1 + \beta x_{i+1})f - x_{i+1}(1 + \beta x_i)s_i f}{x_i - x_{i+1}},$$

and $w = s_{i_1} \cdots s_{i_\ell}$ is some reduced expression. The Lascoux polynomials have no known geometric or representation theoretic interpretations, yet several conjectural combinatorial interpretations.

Goals:

- Construct a $U_q(\mathfrak{sl}_n)$ -crystal structure on set-valued tableaux and relate this to other constructions.
- Construct a K -theoretic analog of crystals on set-valued tableaux.
- Determine a combinatorial interpretation of Lascoux polynomials.

Crystal structure

Let $T \in \text{SV}^n(\lambda)$ and $i \in I := \{1, 2, \dots, n-1\}$. Write $+$ above each column of T containing i but not $i+1$, and write $-$ above each column containing $i+1$ but not i . Cancel ordered pairs $-+$. If every $+$ (resp. $-$) thereby cancels, then $f_i(T) = 0$ (resp. $e_i(T) = 0$). Otherwise, let b be the box corresponding to the leftmost (resp. rightmost) uncanceled $+$ (resp. $-$). Otherwise $f_i T$ (resp. $e_i T$) is given by replacing the i (resp. $i+1$) in b . If the result is not a set-valued tableau, then additionally move the i (resp. $i+1$) in the box immediately to the right (resp. left) into b .

Results

Theorem 1: These crystal operators define a $U_q(\mathfrak{sl}_n)$ -crystal structure on $\text{SV}^n(\lambda)$ such that

$$\text{SV}^n(\lambda) \cong \bigoplus_{\mu \supseteq \lambda} B(\mu)^{\oplus M_\lambda^\mu},$$

where M_λ^μ denotes the number of $T \in \text{SV}^n(\lambda)$ such that $e_i T = 0$ for all $i \in I$ (equivalently, the reading word, where we read the sets in decreasing order, is a Yamanouchi word).

Corollary 2: A. Buch's uncrowding bijection gives a crystal isomorphism such that connected components are indexed by C. Lenart's flagged increasing tableaux.

Theorem 3: There exists a K -crystal structure on set-valued tableau $\text{SV}^n(\lambda)$ when λ is a single row or a single column.

Proposition 4: There does not exist a (strong) K -crystal structure on $\text{SV}^3(21)$.

Marked GT patterns

A **Gelfand–Tsetlin (GT) pattern** is a sequence of partitions $(\lambda^{(j)})_{j=0}^n$ such that $\lambda^{(0)} = \emptyset$ and $\lambda^{(j)}/\lambda^{(j-1)}$ is a horizontal strip. By marking entries certain entries (i, j) provided $\lambda_{i+1}^{(j)} < \lambda_{i+1}^{(j-1)}$, we obtain a bijection with set-valued tableaux.

$$\begin{array}{cccccc} 8 & 7 & 3 & 1 & 0 & \\ & 8 & 5 & 2 & 0 & \\ & & 7 & 5 & 2 & \\ & & & 5 & 3 & \\ & & & & 3 & \end{array} \longleftrightarrow \begin{array}{|c|c|c|c|c|c|c|} \hline 1 & 1 & 1 & 2 & 2 & 3 & 3,4 & 4 \\ \hline 2 & 2 & 2,3 & 3 & 3,5 & 5 & 5 & \\ \hline 3 & 3,4,5 & 5 & & & & & \\ \hline 5 & & & & & & & \\ \hline \end{array}$$

Open problems

- Construct a (weak) K -crystal structure on $\text{SV}^n(\lambda)$.
- Determine a tensor product rule such that the result categorifies the K -theory ring of the Grassmannian.
- Determine a K -jeu de taquin rule such that K -rectification agrees with Buch's insertion algorithm.
- Determine a combinatorial rule that characterizes the set-valued tableaux that appear in $\text{SV}_w^n(\lambda)$ for a given (weak) K -crystal structure.

K-crystal structure

A **K -crystal structure** on $\text{SV}^n(\lambda)$ is a $U_q(\mathfrak{sl}_n)$ -crystal with **K -crystal operators** e_i^K, f_i^K such that

1. $\text{SV}^n(\lambda)$ is connected with unique u_λ of weight λ such that $e_i u_\lambda = e_i^K u_\lambda = 0$ for all $i \in I$,
2. the **K -Demazure crystal**

$$\text{SV}_w^n(\lambda) := \{T \in \text{SV}^n(\lambda) \mid (e_{i_1}^K)^{\max} e_{i_2}^{\max} \cdots (e_{i_\ell}^K)^{\max} e_{i_\ell}^{\max} T = u_\lambda\}$$

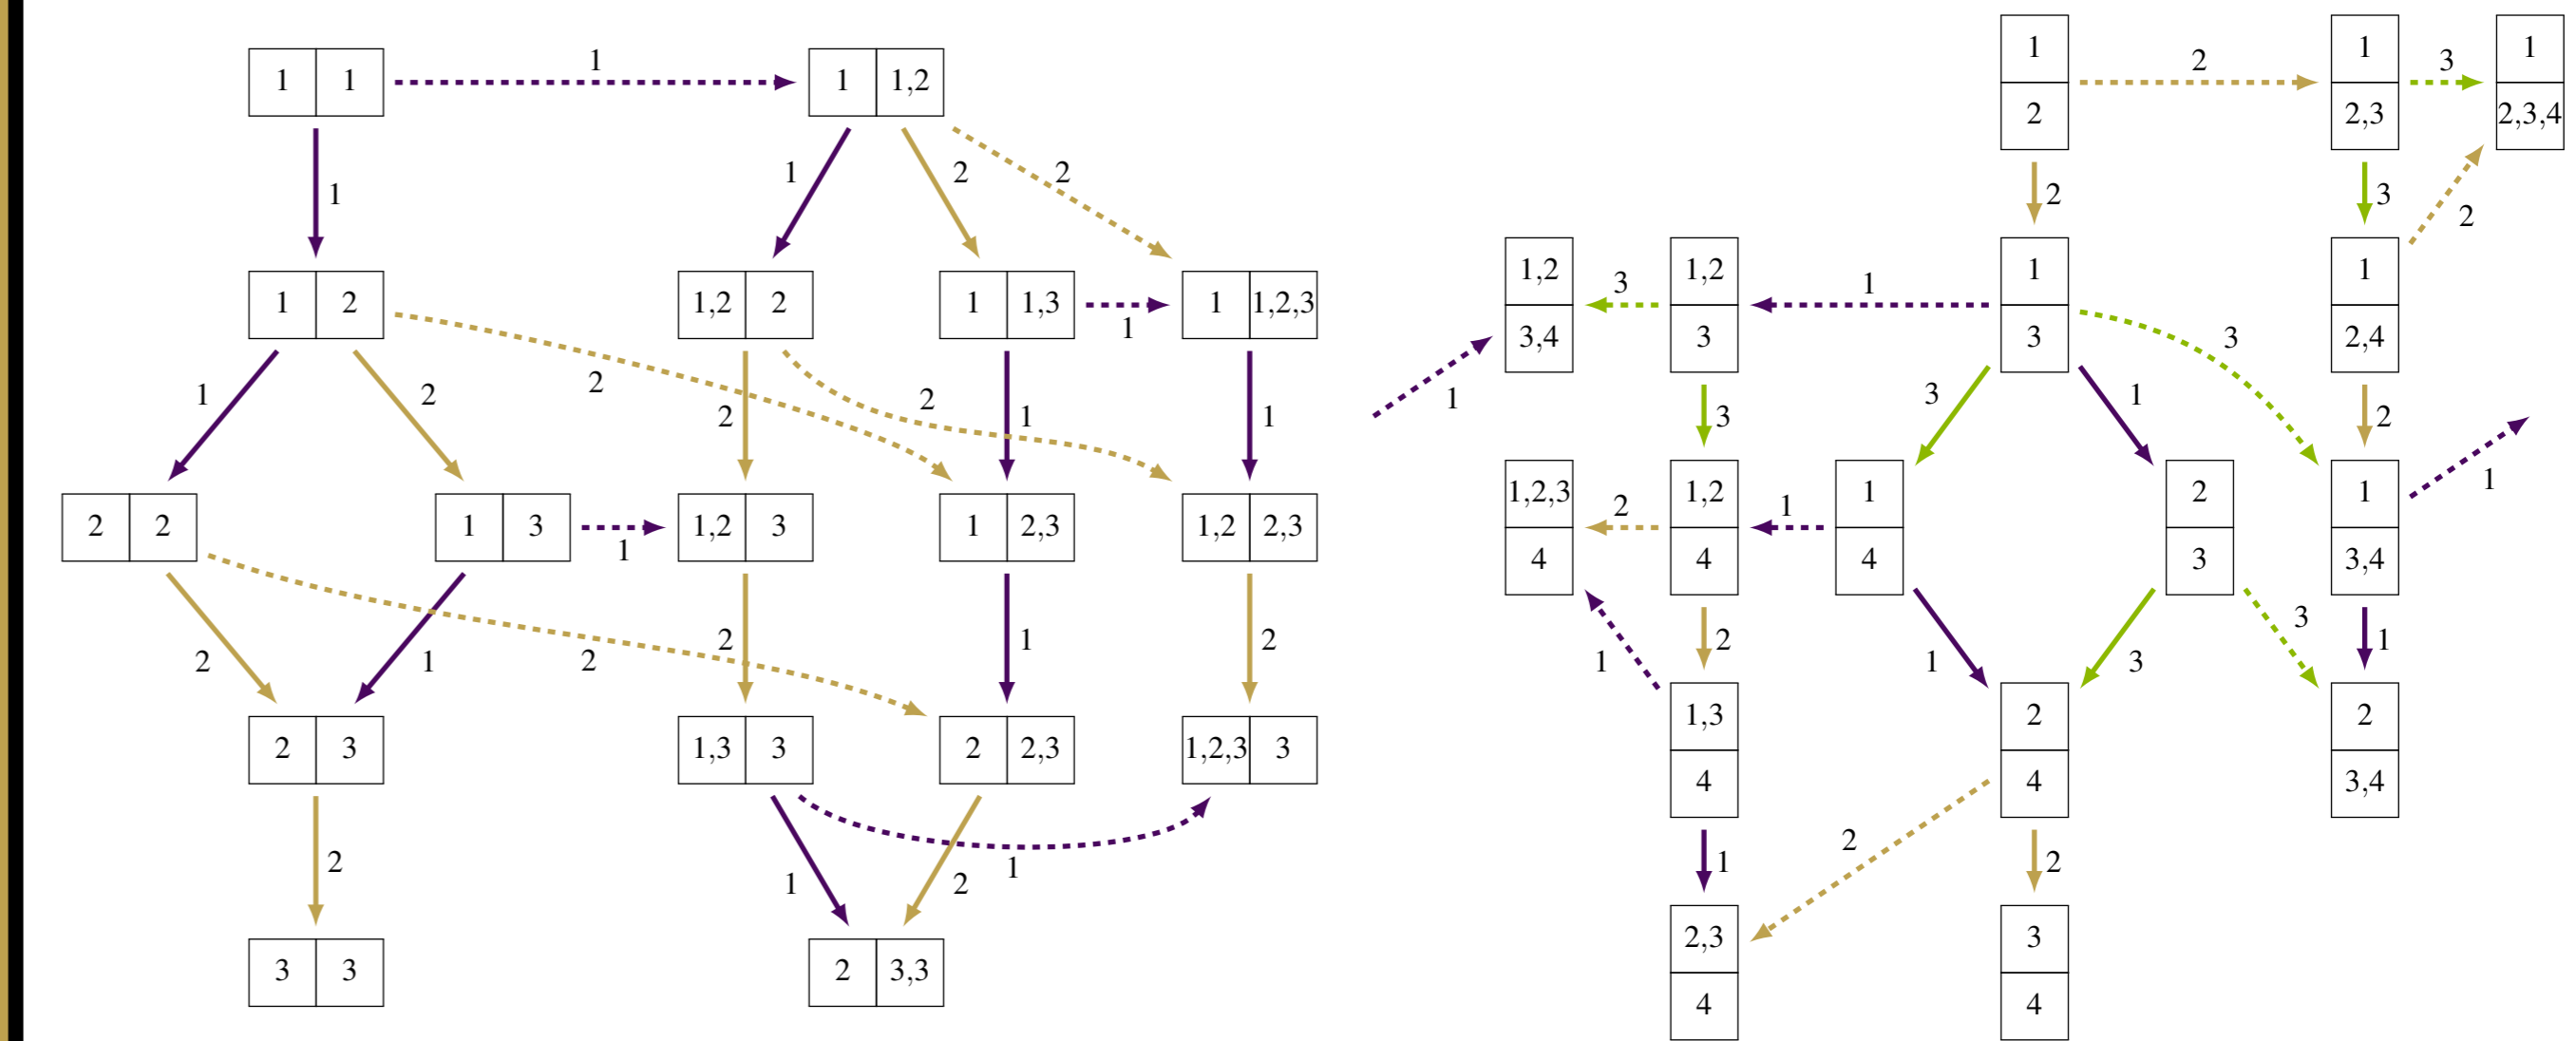

does not depend on the choice of reduced expression $w = s_{i_1} \cdots s_{i_\ell}$, and

3. the character of $\text{SV}_w^n(\lambda)$ is $L_{w\lambda}(\mathbf{x}; \beta)$.

A **weak K -crystal** is when the K -Demazure crystal does depend on the choice of reduced expression and the character is only $L_{w\lambda}(\mathbf{x}; \beta)$ for *some* reduced expression of w .

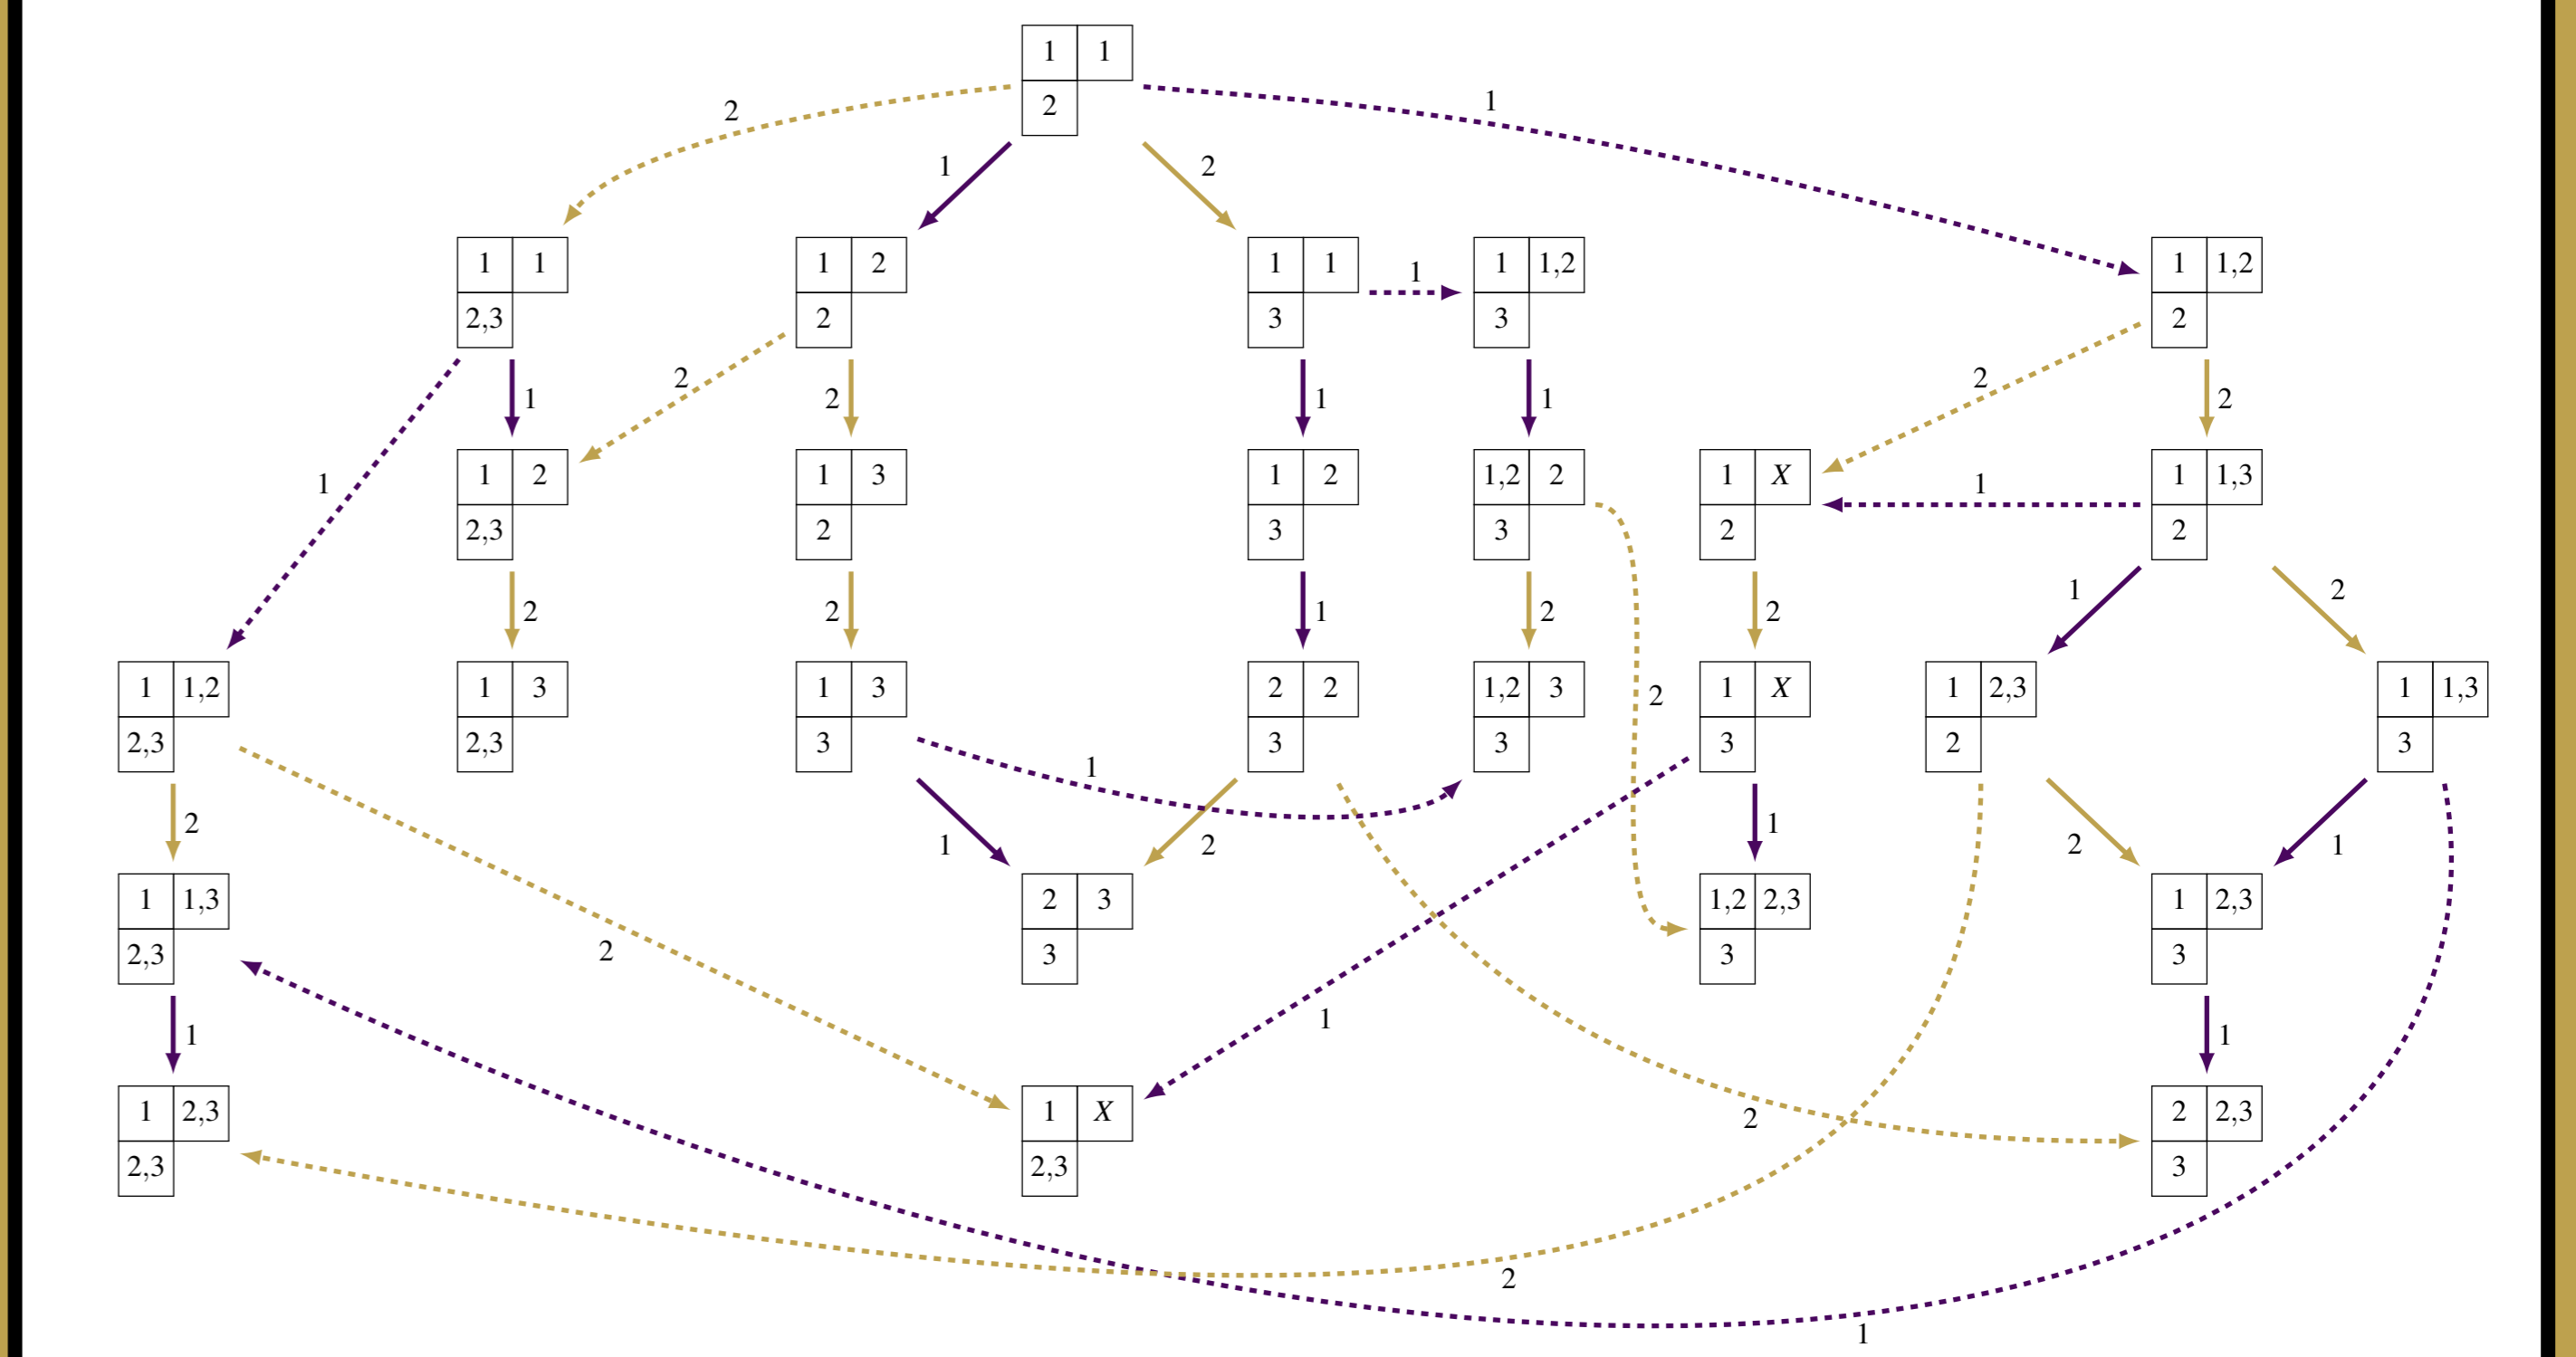

K-crystal examples

The K -crystal structures on $\text{SV}^3(2)$ (left) and $\text{SV}^4(11)$ (right):

Weak K-crystal example

A weak K -crystal structure on $\text{SV}^3(21)$ for the reduced word $w_0 = s_1 s_2 s_1$ (where $X = \{1, 2, 3\}$):

Uncrowding

The uncrowding bijection is given by RSK inserting each row of a set-valued tableau into the previous result and recording the depths of the added boxes.

$$T = \begin{array}{|c|c|c|} \hline 1,2 & 3 & 3,4 \\ \hline 3,5 & 5,6 & \\ \hline \end{array}, \quad \psi(T) = \left(\begin{array}{|c|c|c|} \hline 1 & 3 & 3 \\ \hline 2 & 4 & \\ \hline 3 & 5 & \\ \hline 5 & & \\ \hline 6 & & \\ \hline \end{array}, \begin{array}{|c|c|} \hline 1 & 2 \\ \hline 2 & \\ \hline 4 & \\ \hline \end{array} \right),$$

Rectification

Let U and T be set-valued tableaux of shape λ and μ/λ respectively. We construct the tableau $U \sqcup T$ of shape λ by replacing every letter $k \mapsto \bar{k}$ in U and using the entries in T . Note $U \sqcup T$ is a set-valued tableau in the alphabet $\bar{1} < \bar{2} < \cdots < \bar{m} < 1 < 2 < \cdots < n$. We define operators b_i on set-valued tableaux whose entries are in an alphabet \mathcal{A} . Let j be the letter of \mathcal{A} immediately greater than i . Let t_i be the **K -Bender–Knuth operator** t_i of Ikeda and T. Shimazaki given row-by-row interchanging i and j in each box such that there is not an j in the box below an i or an i in the box above an j and finally reversing all such boxes. Then, b_i acts by first applying t_i to the labels i and j , and then switching all instances of i and j . The **rectification** $\text{rect}_U(T)$ of T (with respect to the rectification order U) is the semistandard tableau obtained by restricting $b_{\bar{1}}^{\circ n} \circ \cdots \circ b_{\bar{m}-1}^{\circ n} \circ b_m^{\circ n}(U \sqcup T)$ to the unbarred alphabet. For an example, we have

$$U \sqcup T = \begin{array}{|c|c|c|c|} \hline 1 & 1,3 & 2 & 2 \\ \hline 2,3 & 1,2 & & \\ \hline 1 & & & \\ \hline \end{array} \xrightarrow{b_3} \begin{array}{|c|c|c|c|} \hline 1 & 1,1 & 2 & 2 \\ \hline 2,1 & 1,2 & & \\ \hline 3 & & & \\ \hline \end{array} \xrightarrow{b_3} \begin{array}{|c|c|c|c|} \hline 1 & 1,1 & 2 & 2 \\ \hline 2,1 & 2,3 & & \\ \hline 3 & & & \\ \hline \end{array} \xrightarrow{b_2} \begin{array}{|c|c|c|c|} \hline 1 & 1,1 & 2 & 2 \\ \hline 1,2 & 2,3 & & \\ \hline 3 & & & \\ \hline \end{array} \xrightarrow{b_2} \begin{array}{|c|c|c|c|} \hline 1 & 1,1 & 2 & 2 \\ \hline 1,2 & 2,3 & & \\ \hline 3 & & & \\ \hline \end{array} \xrightarrow{b_1} \begin{array}{|c|c|c|c|} \hline 1 & 1,1 & 2 & 2 \\ \hline 1,2 & 2,3 & & \\ \hline 3 & & & \\ \hline \end{array} \xrightarrow{b_1} \begin{array}{|c|c|c|c|} \hline 1 & 1,1 & 2 & 2 \\ \hline 1,2 & 2,3 & & \\ \hline 3 & & & \\ \hline \end{array} \xrightarrow{b_1} \begin{array}{|c|c|c|c|} \hline 1 & 1,2 & 2 & 1 \\ \hline 2,1 & 2,3 & & \\ \hline 3 & & & \\ \hline \end{array} \Rightarrow \text{rect}_U(T) = \begin{array}{|c|c|c|} \hline 1 & 1,2 & 2 \\ \hline 2 & & \\ \hline \end{array}.$$

We note that the rectification, in general, depends on the choice of U :

$$T = \begin{array}{|c|} \hline 1 \\ \hline 1,2 \\ \hline \end{array}, \quad \bar{U} = \begin{array}{|c|} \hline \bar{1} \\ \hline \end{array}, \quad \bar{V} = \begin{array}{|c|} \hline \bar{1}, \bar{2} \\ \hline \end{array}, \quad \text{rect}_{\bar{U}}(T) = \begin{array}{|c|} \hline 1 \\ \hline 2 \\ \hline \end{array}, \quad \text{rect}_{\bar{V}}(T) = \begin{array}{|c|} \hline 1,2 \\ \hline \end{array}.$$
